Abstract- A natural phenolic compound namely pyrocatechic acid or 2,3-dihydroxybenzoic acid has been known for its biological activity as antioxidant and antimicrobial agent. This compound shows a potential chelating ability to bind metal ions through its three oxygen donor atoms. This ability seems to be promising for metal intoxication by chelation. In this study, the chelating ability of PA towards metal ion was expressed as “equilibrium constant” which showed the stability of the chelate complex formed. The investigated metal ions are Cu$^{2+}$, Zn$^{2+}$, and Mn$^{2+}$. Potentiometric method was used for the determination of the equilibrium constant. The potentiometric method was carried out in aqueous solution which mimics human body fluid, with ionic strength of 0.15 mol dm$^{-3}$ NaCl at temperature 37°C. The formation of chelate complex was confirmed by spectrophotometric measurements. The result showed that the two oxygen donor atoms from hydroxyl group of PA were found to bind the metal ion. The stability of the metal complexes were increased as the ionic radius of the metal ion is decreased, where the complex that has highest stability is Cu$^{2+}$ > Zn$^{2+}$ > Mn$^{2+}$. Additionally, the species distribution of the metal complexes in function of pH was presented graphically by using HySS2009.

Keywords- Chelate Complex, Potentiometric, Stability Constant, Pyrocatechic Acid, 2,3-Dihydroxybenzoic Acid.

I. INTRODUCTION

Pyrocatechic acid (2,3-dihydroxybenzoic acid) is a phenolic compound which possesses three oxygen donor atoms that were found to be potential to bind metal ions [1], [2]. In nature, pyrocatechic acid can be found in some sources such as aquatic fern Salvinia molesta, Platycodon grandiflorum, Phyllanthus acidus and Vitex trifoli [3]. PA was found to present in human body as the result of aspirin metabolism and also provides some health benefit such as antioxidant and antimicrobial [4]. As a chelating agent, PA may help to bind some excess of non-degradable trace elements (such as metals), make them easier to excrete from body and prevent poisoning due to metal accumulation in high concentration.

As depicted in Fig. 1, pyrocatechic acid possesses three active oxygen donor atoms in carboxylic group and the other two in hydroxyl group at ortho and meta position. These three oxygen atoms were considered as active donor groups due to their deprotonable H$^+$ atom.

![Figure 1. Structure of 2,3-dihydroxybenzoic acid](image)

In this study, some of divalent metal ions namely Cu$^{2+}$, Zn$^{2+}$, and Mn$^{2+}$ were investigated. These trace elements were needed in very small amount to balance human metabolism, these elements also known as micronutrients [5]. Excess amount of these trace elements may lead to heavy metal poisoning and may cause several adverse health effects such as metabolism disorders and cells disruption [6], [7]. The introduction of an organic compound as a ligand may help to control the concentration of these trace elements in the body and prevent heavy metal poisoning [8], [9]. The ligand have ability to chelate metal ion by its donor atom. Stability constant is an important property of chelation which gives impression about the stability of the binding. Thus, higher stability constant value indicating the more stable the chelation between the ligand and the metal ion. The formation of metal complex is pH dependent, different species of metal complex may form in different pH.

In this study the chelating ability of pyrocatechic acid towards some divalent metal ions (Cu$^{2+}$, Zn$^{2+}$, and Mn$^{2+}$) expressed in stability constant value were determined. Potentiometric measurement was used in this study. The study was done in aqueous solution with constant ionic strength of 0.15 mol dm$^{-3}$ NaCl and temperature 37°C. The investigated pH is in the range of 2.5 to 11.0, the species distribution of the system was also graphically presented in this pH range. Spectrophotometric method was done in wavelength range of 400-800 nm for qualitative measurement.

II. EXPERIMENTAL PROCEDURE

A. Materials and Solutions
All chemicals were analytical grade and used without further purification. Pyrocatechic acid (C$\text{H}_\text{3}$OH, 98% purity) was purchased from Alfa Aesar (UK). Sodium chloride (NaCl, 99.5% purity) was obtained from Showa (Japan). Manganese chloride tetrahydrate (MnCl$_2$$\cdot$4H$_2$O, 99.8%) and sodium hydroxide (NaOH,
99% purity) were supplied by Yakuri (Japan). Hydrochloric acid (HCl, 37.6% purity) was purchased from Fisher Scientific (USA). Carbonate-free NaOH and HCl were prepared and standardized before used. Copper chloride dehydrate (CuCl₂, 2H₂O, 99% purity) and zinc nitrate hexahydrate (Zn(NO₃)₂.6H₂O, 98%) were obtained from Sigma Aldrich (USA). All solutions were prepared freshly before experiments using ultra pure water obtained from NANO Pure Ultrapure water (18.3 MΩ·cm⁻¹).

B. Potentiometric Method

Potentiometric titrations were carried out in a 100 cm³ commercial double walled glass vessel and thermostatted at 310.15 K by the circulating water bath. The titration were performed by using a Metrohm autotitrator 888 Titrando with a 805 Dosimat with exchange unit, a 802 rod stirrer supported with 804 Ti stand. The device was coupled to a personal computer and the titration software Tiamo 2.3 to control the titration process and record the data. The following solutions were prepared in each 50 cm³ for the titration, ±1·10⁻³ mol·dm⁻³ carbonate-free NaOH was used as the titrant to adjust the pH from 2.5 to 11.0.

a. 3·10⁻³ mol·dm⁻³ HCl + 1.5·10⁻¹ mol·dm⁻³ NaCl + 1·10⁻³ mol·dm⁻³ Ligand
b. 3·10⁻³ mol·dm⁻³ HCl + 1.5·10⁻¹ mol·dm⁻³ NaCl + Ligand + metal salt (Cu²⁺, Zn²⁺, and Mn²⁺)

The solution b was prepared at metal to ligand molar ratios of 1:1; 1:2; 1:2.5 and 1:3 to cover all possible coordination number. Ionic strength of the solutions was maintained at 1.5·10⁻¹ mol·dm⁻³ with NaCl as the supporting electrolyte. Each titration was repeated at least 3 times, with repeatability of ±0.002 pH units. The titration curves were processed by Hyperquad2008 program for the refinement of stability constants. The species distribution diagram of the formed species at pH range of 2.5 to 11.0 was simulated by using HySS2009 simulation program.

C. Spectrophotometric Measurements

The spectrum measurements were carried in a standard quartz cell and JASCO V-550 spectrophotometer, with wavelength range of 400-800 nm. Solution containing 2.5·10⁻⁵ mol·dm⁻³ of metal salt (Cu²⁺/Zn²⁺/Mn²⁺) and 5·10⁻⁴ mol·dm⁻³ ligand PA was prepared for the measurement. ±1·10⁻⁴ mol·dm⁻³ carbonate-free NaOH was used to adjust the pH from 2.5 to 11.0.

D. Data Analysis

The stability of metal complex known as overall stability constant “β” can be computed from some parameter such as total concentration of the metal ion [M] and the ligand [L] can be defined as

\[ \beta = \frac{[ML]}{[M][L]} \]

Where “M” is the metal ion, “L” is the ligand and “H” is the hydrogen atom involved in the formation of a metal complex.

By using Hyperquad2008 program, not only the ML species stability constant can be determined. Various species such as MLH₂, MLH and ML₂ also can be determined. The stability constant from Hyperquad2008 was presented as overall stability constant (logβ), expressed as

\[ pM + qL + rH \leftrightarrow M_q^+ L_r^- H_p^{-} \]

\[ \beta_{pqr} = \frac{[M_q^+ L_r^- H_p^{-}]}{[M][L]^q[H]^r} \]  

Where the coefficient p, q, r represent the number of metal ion, ligand and hydrogen atom respectively [10].

III. RESULT AND DISCUSSION

A. Protonation Constant of Pyrocatechuic acid

From the Hyperquad2008, the protonation constant represented as overall formation constant (logβ). Pyrocatechuic acid is the trisubic ligand (H₃L) which possesses three oxygen donor atom at carboxyl (COOH) group, hydroxyl (OH) group at ortho and meta position respectively o-OH and m-OH. The formation equilibrium can be expressed as:

H + L \leftrightarrow HL ; \beta = [HL]/[H][L]
2H + L \leftrightarrow H₂L ; \beta = [H₂L]/[H]²[L]
3H + L \leftrightarrow H₃L ; \beta = [H₃L]/[H]³[L]

Where the protonation constant or stepwise formation constant “logKa” can be described as logβ₁= logKa₁; logβ₂= logKa₂+ logKa₁; and logβ₃= logKa₃+ logKa₂+ logKa₁. The logK values were presented in Table 1.

As depicted in Fig. 2, the first protonation of pyrocatechuic acid to form H₂L was take place at basic pH. This protonation was occurred due to attachment of H⁺ atom to oxygen donor atom at ortho position with logKa₁ value of 13.00. Followed by the protonation of m-OH to formed H₃L with logKa₂ value of 9.98.

Finally the H₃L was formed from the attachment of H⁺ atom of the COOH group with logKa₃ value of 2.63. The logβ₁, logβ₂, and logβ₃ values from Hyperquad2008 refinement are 13.00, 22.98 and 25.56.
respectivey.

**B. Stability Constant of Metal Complex**

The titration curve of the Ligand (L) system only, Cu\(^{2+}\)-ligand, Zn\(^{2+}\)-ligand, and Mn\(^{2+}\)-ligand was shown in Fig. 3. The metal-ligand system show deviation from the L system indicated that a new species is formed in the system. The titration curve of Cu\(^{2+}\) showed greater deviation from the L titration curve than Zn\(^{2+}\) and Mn\(^{2+}\) system indicated that Cu\(^{2+}\) have greater interaction with the ligand which is resulting better stability of the chelate complexes later.

![Figure 3. Titration curve of the system with metal to ligand ratio 1:2. ▲, Ligand system; △, Cu\(^{2+}\)-ligand system; ◇, Zn\(^{2+}\)-ligand system; ▼, Mn\(^{2+}\)-ligand system;](image)

The stability constant of the divalent metal ions (Cu\(^{2+}\), Zn\(^{2+}\), and Mn\(^{2+}\)) with pyrocatechlic acid was refined by Hyperquad2008. Several possible metal complex species were introduce to the program, and the species those gave the best statistical fitting with the data was selected. It was found that [ML\(_2\)], [MLH], [ML], and [ML\(_2\)] species is present in the system. The stability constant value was presented in \(\log \beta_{pqr}\) as shown in Table 2. The species distribution of each system in metal to ligand ratio of 1:2, was graphically presented in Fig. 3.

The \(\log \beta_{pqr}\) show that Cu\(^{2+}\) complex is stronger than Zn\(^{2+}\) and Mn\(^{2+}\). Observed from ML species the \(\log \beta_{110}\) value for Cu\(^{2+}\) is 15.00, Zn\(^{2+}\) \(\log \beta_{110}\) = 10.48 and Mn\(^{2+}\) \(\log \beta_{110}\) = 8.41. This order is in an agreement with Irving William series where Cu\(^{2+}\) > Zn\(^{2+}\) > Mn\(^{2+}\) [12]. The \(\log \beta\) value is increasing with the increasing of atomic number, where the atomic number of Mn\(^{2+}\) is 25, Cu\(^{2+}\) is 29, and Zn\(^{2+}\) is 30. Cu\(^{2+}\) have higher stability even the atomic number is smaller than Zn\(^{2+}\) due to the distortion correlated to Jahn-Teller effect which always occurs in Cu\(^{2+}\) complexes.

In the Cu\(^{2+}\) system, as shown in species distribution in Fig. 3(a), the CuLH\(_3\) species were formed in initial acidic pH 2.5. Thus, this species were formed from the binding with COOH group, where at this pH only COOH group is available at deprotonated donor atom. The formation of CuLH, CuL were take place in lower pH than ZnLH and MnLH, indicated that the interaction of the ligand with Cu\(^{2+}\) is stronger than with Zn\(^{2+}\) and Mn\(^{2+}\). CuL\(_2\) species were formed in quite similar pH with ZnL\(_2\) and MnL\(_2\).

In the Zn\(^{2+}\) system and Mn\(^{2+}\) system as shown in Fig. 3(b) and (c), the species distribution are quite similar. The species MLH\(_2\) is the initial species that occurred in the system. This species is formed by the binding of O donor atom from COOH group, since the formation is take place in lower pH than ZnLH and MnLH, indicated the interaction of the ligand with Cu\(^{2+}\) is stronger than with Zn\(^{2+}\) and Mn\(^{2+}\). CuL\(_2\) species were formed in quite similar pH with ZnL\(_2\) and MnL\(_2\).
that the interaction of the second ligand (same species) to form ML₂ is weaker than the first ligand. However, overall the stability of ML₂ complex is higher than ML. The lower logK₂ value also indicated that the ML₂ complex is formed; in which this will resulting in negative ΔlogK. Where, ΔlogK=logK₂-logK₁.

C. Spectrophotometric Measurement
Spectrophotometric measurements were done to qualitatively observe the shifting of the metal-ligand system spectrums. The spectrums correspond to the d-d transition were measured in wavelength range of 400-800 nm as shown in Fig. 5.

In Cu²⁺ (d⁹) system, the species CuLH were formed in acidic pH and caused higher intensity in the spectrum compared to Co²⁺ and Ni²⁺ system. The formation of CuL and CuL₂ were gave higher intensity. The band transitions at pH 11.0 were observed at wavelength 452 nm and 721 nm which corresponding to ²A₁g→²B₁g and ²E→²B₁g respectively.

In Zn²⁺ (d¹⁰) system, intensely low intensity spectrums were observed. This is due to Zn²⁺ does not have orbital transition, since as d¹⁰ atom the electrons have filled all the orbital. In Mn²⁺ (d⁵) system, at low pH 3.0-6.0 the spectrum intensity is lower. Where at this pH the species formed is MnLH₂ species. The species MnLH, MnL and MnL₂ give higher intensity which observed in higher pH start from pH 7.0. The higher spectrum observed at pH 11.0 the, in this pH the bands are observed at wavelength 661 nm, correspond to the transition of ⁶A₁g(S)→⁴T₁g(g).
Complex Stability in Aqueous Solution of Metal Ions (Cu$^{2+}$, Zn$^{2+}$, and Mn$^{2+}$) with Pyrocatechuic Acid Ligand

CONCLUSION

Potentiometric measurement was used for the determination of stability constant between pyrocatechuic acid and divalent metal ion (Cu$^{2+}$, Zn$^{2+}$, and Mn$^{2+}$). The measurements were done in aqueous solution with constant ionic strength of 0.15 mol·dm$^{-3}$ NaCl and temperature of 37°C. The ligand pyrocatechuc acid is the tribasic (H$_3$L) ligand which has three active donor groups. The first group is OH at ortho position with log$K_{a1}$ value 13.00, second is OH at meta position with log$K_{a2}$ of 9.98 and third is COOH group with log$K_{a3}$ value 2.63. The stability constants were decrease in order of Cu$^{2+}$ > Zn$^{2+}$ > Mn$^{2+}$, where Cu$^{2+}$ complexes are the most stable. This order is affected by the atomic number of the metal ion and also Jahn-Teller distortion. The complexes observed in the form of MLH$_2$, MLH, ML and ML$_2$ species. The formation of the metal complexes causes a shifting in the spectrum, where the greater intensity of the spectrum was observed in pH 11.0.
